Keywords:	evapotranspiration, water management, irrigation scheduling
Abstract:	The Accurate daily reference evapotranspiration (ET) values are needed to estimate crop water demand for irrigation management and hydrologic modeling purposes. The Bushland Reference ET Calculator (BET) was developed to implement a user-friendly interface for calculating hourly and daily grass and alfalfa reference ET using the Java Programming Language. The calculator uses the American Society of Civil Engineers (ASCE) Standardized Reference ET equation for calculating both grass and alfalfa reference ET at hourly and daily time steps from a single set or time series of weather data. Daily reference ET can be calculated either by calculating the hourly reference ET values and summing them up or by calculating a daily value using daily statistics of the climatic data (means, maxima and minima). Graphing capabilities include line graph and scatter plot for quality assurance and quality control purposes. Descriptive statistics can be calculated for selected or all of the variables. Although the "Bushland Reference ET Calculator" was designed and developed for use mainly by producers and crop consultants to manage irrigation scheduling, it can also be used in educational training, research, and other practical applications. This paper demonstrates the use of the Bushland Reference ET Calculator that is available from the USDA-ARS Conservation and Production Research Laboratory web site to interested users at no cost.

ABSTRACT.

The Accurate daily reference evapotranspiration (ET) values are needed to estimate crop water demand for irrigation management and hydrologic modeling purposes. The Bushland Reference ET Calculator (BET) was developed to implement a user-friendly interface for calculating hourly and daily grass and alfalfa reference ET using the Java Programming Language. The calculator uses the American Society of Civil Engineers (ASCE) Standardized Reference ET equation for calculating both grass and alfalfa reference ET at hourly and daily time steps from a single set or time series of weather data. Daily reference ET can be calculated either by calculating the hourly reference ET values and summing them up or by calculating a daily value using daily statistics of the climatic data (means, maxima and minima). Graphing capabilities include line graph and scatter plot for quality assurance and quality control purposes. Descriptive statistics can be calculated for selected or all of the variables. Although the "Bushland Reference ET Calculator" was designed and developed for use mainly by producers and crop consultants to manage irrigation scheduling, it can also be used in educational training, research, and other practical applications. This paper demonstrates the use of the Bushland Reference ET Calculator that is available from the USDA-ARS Conservation and Production Research Laboratory web site to interested users at no cost.

Keywords. Irrigation Scheduling, Bushland Reference ET Calculator; Water Management

INTRODUCTION

Evapotranspiration (ET) is defined as a measure of the total water consumption through evaporation from the soil and plants and transpiration by plants. In agriculture, ET is a major consumptive use of irrigation water and precipitation.

51 | Reliable and accurate estimates of ET or crop water use are essential to optimize irrigation management. [Potential water](#)
 52 | use by a specific crop (ET_c) can be estimated by multiplying daily reference ET by an appropriate crop coefficient (K_c)
 53 | derived from [field measurements based on](#) water balance [methods](#), including lysimetry (Marek et al., 2010). [Then, \$ET_c\$ can](#)
 54 | [be estimated by multiplying reference ET with \$K_c\$](#) under the assumption that weather conditions for the reference crop
 55 | surface are similar to (representative of) those within the surrounding region. [Reference ET](#) refers to the amount of water
 56 | that would be lost to the atmosphere from a hypothetical grass or alfalfa crop grown under reference conditions; water and
 57 | nutrients not limiting and the crop maintained at the reference height and full cover (Allen et al., 1998). [Reference ET](#) is
 58 | attributed directly to the atmospheric water demand irrespective of crop type. Consequently, ET_{ref} can be calculated using
 59 | meteorological data from solar radiation (R_s), wind speed (U_2), air temperature (T_a), and relative humidity (RH).

60 | [Prior](#) to the [reference ET](#) concept, several equations [with](#) varying complexity and input requirements were developed to
 61 | calculate what was termed as potential ET (ET_o), a closely related concept. For example, ET_o formulations proposed by
 62 | Blaney and Criddle (1950), Makkink (1957), and Priestley and Taylor (1972) required only solar radiation, and that
 63 | proposed by Hargreaves and Samani (1985) required only air temperature. Other methods such as Allen et al. (1998),
 64 | Doorenbos and Pruitt (1977), Monteith (1965), and Penman (1948) required some combinations of parameters involving
 65 | solar radiation, air temperature, humidity, and wind speed (Er-Raki et al., 2010). In the United States, in order to
 66 | standardize reference ET calculation and allow for transferability of crop coefficients, the ASCE-[EWRI](#) Standardized
 67 | Reference Evapotranspiration Equation ([\$ET_{sz}\$](#)) (Allen et al., 2005) was established as the benchmark equation. This
 68 | equation is a simplified [version of the Penman-Monteith \(PM\) ET equation given in ASCE Manual 70 \(Jensen et al., 1990\)](#)
 69 | with appropriate constants for two standardized reference crop surfaces: [\(1\) short, smooth crop similar to clipped grass](#)
 70 | [with an approximate height of 0.12 m and \(2\) a taller, rough agricultural crop similar to full-cover alfalfa with an](#)
 71 | [approximate height of 0.50 m](#) (Walter et al., 2000). [Provision and recommendations are made for application of the](#)
 72 | [equation including standardized calculations for all intermediate parameters at hourly and daily time steps. In addition,](#)
 73 | [guidelines are provided for assessing integrity of weather data used for estimating reference ET and methodologies that](#)
 74 | [can be used where data is limited or missing.](#) Currently, it is one of the most widely used equations to calculate [reference](#)
 75 | [ET](#) for either a short reference crop (clipped grass - ET_{os}) or a tall reference crop (alfalfa - ET_{rs}) in the United States.

76 | The [ASCE](#) standardized reference ET (ET_{sz}) equation (Allen et al., 2005) is given as:

$$77 \quad ET_{sz} = \frac{0.408 \Delta (R_n - G) + \gamma \frac{c_n}{T + 273} u_2 (e_s - e_a)}{\Delta + \gamma (1 + c_d u_2)} \quad (1)$$

78

79 where: ET_{sz} is the standardized reference ET for grass (ET_{os}) or alfalfa (ET_{rs}) crop surfaces ($mm\ d^{-1}$ for daily or $mm\ h^{-1}$
80 for hourly time steps), R_n is the net radiation at the crop surface ($MJ\ m^{-2}\ d^{-1}$ for daily or $MJ\ m^{-2}\ h^{-1}$ for hourly time steps), G
81 is the soil heat flux density at the soil surface ($MJ\ m^{-2}\ d^{-1}$ for daily or $MJ\ m^{-2}\ h^{-1}$ for hourly time steps), T is the mean daily
82 or hourly air temperature at 2-m height ($^{\circ}C$), u_2 is the mean daily or hourly wind speed at 2-m height ($m\ s^{-1}$), e_s is the
83 mean hourly saturation vapor pressure (kPa) at 2-m height for hourly calculations or is calculated for daily time steps as
84 the average of saturation vapor pressure at maximum and minimum air temperatures, e_a is the mean actual vapor pressure
85 (kPa) at 2-m height, Δ is the slope of the saturation vapor pressure-temperature curve ($kPa\ ^{\circ}C^{-1}$), γ is the psychrometric
86 constant ($kPa\ ^{\circ}C^{-1}$), C_n is the numerator constant that changes with reference type and calculation time step ($K\ mm\ s^3\ Mg^{-1}$
87 d^{-1} or $K\ mm\ s^3\ Mg^{-1}\ h^{-1}$), C_d is the denominator constant that changes with reference type and calculation time step ($s\ m^{-1}$),
88 and units for the 0.408 coefficient are $m^2\ mm\ MJ^{-1}$. The values for C_n and C_d are provided in Table 1 of the manual of the
89 ASCE standardized reference ET equation (Allen et al., 2005).

90 Numerous studies have been conducted to [compare \$ET_{sz}\$ with other widely used methods. Detail discussion on the](#)
91 [major differences between these equations in relation to \$ET_{sz}\$ is presented in the Appendix B of the ASCE-EWRI](#)
92 [standardized reference ET equation manual \(Allen et al., 2005\)](#). For example, Itenfisu et al. (2003) conducted a
93 comparison study of commonly used reference ET equations using meteorological measurements from 49 stations in 16
94 states. They found that the daily ET_{os} calculated using [the \$ET_{sz}\$](#) and [FAO-56_PM](#) equations closely matched with ET_{os}
95 calculated with the full form of ASCE-PM equation. [This is expected as FAO-56 PM equation is essentially identical to](#)
96 [procedures provided for calculating \$ET_{sz}\$, except the constant surface resistance value. In ASCE standardized reference ET](#)
97 [equation, the value of the constant surface resistance term used for calculating \$ET_{os}\$ is \$70\ s\ m^{-1}\$ for daytime and \$200\ s\ m^{-1}\$](#)
98 [for night time whereas in FAO-56 PM equation, it is \$70\ s\ m^{-1}\$ for all time steps.](#) They also found that daily ET_{rs} values
99 calculated using the [\$ET_{sz}\$](#) ($0.058\ mm\ d^{-1}$) had much less deviation than that with the 1982 Kimberly Penman equation
100 ($0.267\ mm\ d^{-1}$). Numerous studies (Irmak et al., 2008; Lu et al., 2005; Itenfisu et al., 2003, Xu and Singh, 2002) have
101 indicated that accuracy of [reference](#) ET estimates vary with weather parameters used in the calculation. Irmak et al. (2008)
102 recommended the use of [\$ET_{sz}\$](#) equation when reliable meteorological data are available.

103 ET_{sz} and ET_c estimates that are based on the ASCE-[EWRI](#) standardized [reference ET](#) equation are available to growers
104 for irrigation scheduling in a few parts of the world such as California (the California Irrigation Management Information
105 System, CIMIS, <http://www.cimis.water.ca.gov/cimis/infoEtoOverview.jsp>), Nebraska (the Nebraska Agricultural
106 Management Network, Irmak et al., 2010), Oklahoma (the Oklahoma Environmental Monitoring Network, MESONET,
107 Liu et al., 2011), and Texas (the Texas High Plains ET (TXHPET) Network; Porter et al., 2012). Due to worsening
108 resource constraints, availability is limited and in some cases declining. For example, the TXHPET provided ET_{ref} and ET_c

109 on a daily basis to producers and crop consultants at no cost for over 20 years; however, this service was recently limited
110 due to reductions in funding support. As a consequence, some affected producers, agronomic consultants and researchers
111 are substituting alternative weather data sources to estimate reference ET (with less accuracy). Because the ASCE
112 standardized PM equation is complex to use, even for experienced practitioners not to mention producers and crop
113 consultants, ET_c estimates needed for irrigation scheduling are less reliable than desired.

114 Numerous reference ET calculators with user-friendly interfaces are available and discussed in the literature (Allen,
115 2013; Raes, 2009; Snyder and Eching, 2008). The REF-ET for Windows is one of the widely used commercial reference
116 ET calculator developed by Allen (2013) and distributed through the Idaho Agricultural Experiment Station. Although
117 REF-ET can be used to estimate reference ET with numerous ET formulations including the ASCE standardized PM
118 equation and varying QA/QC procedures associated with different data formats and time-steps, it can be intimidating for
119 producers and agronomic consultants to use as it is not intuitive. Moreover, use of this software requires proficiency in the
120 use of spreadsheets to calculate single hourly and daily ET_{os} and/or ET_{rs} , and users should have a sufficient understanding
121 of different ET models and input requirements. The ET_o Calculator (v3.1) by Raes (2009) uses only the FAO-PM equation
122 for estimating ET_{ref} . Moreover, “average” producers were not the primary target audience for this software. The Hourly
123 Reference Evapotranspiration (ET_o) Calculator (HRPM) (Snyder and Eching, 2008) calculates only ET_{os} at hourly
124 intervals using the ASCE standardized PM equation and daily ET_{os} can be obtained by summing up the calculated hourly
125 values. In addition, it does not have the option to calculate either ET_{rs} at any time-step or ET_{os} directly from daily average
126 weather datasets. In 2010, the ASCE ET Steering Committee identified a need for a user-friendly ET calculator targeting
127 advanced agricultural producers and crop consultants. There is an immediate need for a simple reference ET calculator
128 that can be used by crop consultants and producers to estimate accurate reference ET and representative crop water use
129 with locally available weather data for irrigation scheduling purposes, thereby assisting in implementing the latest water
130 conservation and best management practices. Our objective was to develop a simple and user-friendly reference ET
131 calculator to assist producers and agronomic consultants as well as researchers with minimal or no training.

132 MATERIALS AND METHODS

133 The reference ET calculator designed and developed in this study is named the “Bushland Reference ET Calculator
134 (BET).” The BET uses the ASCE standardized PM equation (Allen et al., 2005) for calculating both ET_{os} and ET_{rs} at
135 hourly and daily time steps. Since clear-sky solar radiation is needed for implementing the standardized equation, BET
136 uses a more complex equation provided in Appendix D of the ASCE standardized ET manual (Allen et al., 2005).

137 BET was developed using the Java Programming Language for calculating both ET_{os} and ET_{rs} . It was designed to

138 provide users with an option of using a single set of time series weather data to calculate ET_{os} and ET_{rs} . Daily ET_{os} and
 139 ET_{rs} can be calculated either by summing the hourly ET_{ref} values for a given day or by using daily averages of the climatic
 140 data. Therefore, it consists of two static and four user-friendly interactive pages. Two static informational pages provide
 141 BET version, citation, contact information for technical support, and USDA disclaimer. Figures 1(a-b) illustrate two static
 142 pages: Home page and About Us. The home page comes up on the computer screen when a user clicks on the BET
 143 software icon. It mainly gives the version of the software that the user is using for the ET_{ref} calculation. The About Us
 144 page provides a short description of the BET, developer's contact information, USDA-ARS' Disclaimer statement, and
 145 citation for the BET.

146 **Figure 1. Static informational pages for the Bushland Reference ET Calculator (BET).**

147 Interactive pages were designed for novice computer users to perform each of the following four tasks: (1) Hourly ET –
 148 Single Calculation, (2) Daily ET – Single Calculation, (3) Hourly and Daily ET - Time Series, and (4) Daily ET – Time
 149 Series. Efforts were made to design the interactive pages for intuitively entering the data input. Further, to ensure correct
 150 weather data are entered and submitted for calculating ET, validation controls were written into the code. When the
 151 program is executed with unreasonable, incomplete or missing data for performing a calculation, validation code resets the
 152 program and prompts the user's attention to the use by bringing up an error message box containing specific information
 153 on the erroneous input data. Also, codes were written to include and show boundary values for each of the input
 154 parameters when the mouse is moved over text boxes assigned for entering the data. An error message will be displayed
 155

156 when a calculation is performed with an input value for a parameter that is outside the set boundary values.

157 Figure 2a illustrates an interactive page for calculating single hourly ET_{os} and ET_{rs} values. Parameters required for the
 158 single hourly calculation of ET_{os} and ET_{rs} include latitude and longitude (deg.-decimals), elevation (m), year and day of
 159 the year (DOY), hour for which ET_{ref} is to be calculated, air and dew point temperatures (deg. C), relative humidity (%),
 160 solar radiation ($W\ m^{-2}$), wind speed (m/s), and barometric pressure (kPa). Year and DOY values can be fed interactively
 161 using the Calendar button provided right next to the Year input box. If the dew point temperature value is not available, it
 162 can be calculated by clicking on the Calculate button right next to the Dew point temperature box provided the air
 163 temperature and relative humidity boxes are entered. In the case of missing relative humidity value, it can be calculated
 164 provided the air and dew point temperature boxes are entered. Barometric pressure can be calculated using the elevation
 165 data if it is not available. Equations used in the calculation of missing dew temperature, relative humidity or barometric
 166 pressure can be found in Allen et al. (2005).

a. Single hourly ET_{ref} calculation

b. Single daily ET_{ref} calculation

167 **Figure 2. Interactive pages in the Bushland Reference ET Calculator (BET) for calculating single hourly and daily ET_{ref} values.**

168

169 Figure 2b illustrates an interactive page for calculating single daily ET_{os} and ET_{rs} values. Input parameters required for
 170 calculating ET_{ref} at the daily time-steps include latitude (deg.-decimals), elevation (m), year and day of the year (DOY),
 171 minimum and maximum air temperatures (deg. C), average dew point temperatures (deg. C), average relative humidity
 172 (%), average solar radiation ($MJ\ m^{-2}\ d^{-1}$), average wind speed (m/s), and barometric pressure (kpa). As in the case of
 173 hourly calculation, average values of dew point temperature, relative humidity, solar radiation, and barometric pressure

174 can be estimated if the measured data are not available. In case of relative humidity and dew point temperature, values
 175 cannot be calculated for both. Either relative humidity or dew point temperature must be known. A message box will
 176 appear requesting the missing data if the user tries to calculate one without entering a value for the other parameter. The
 177 user should note that the unit used for average solar radiation is different from that used in the calculation of hourly ET
 178 value.

179 Figure 3a illustrates an interactive page for calculating hourly and daily ET using hourly time series weather data. In
 180 this interactive page, the user provides time series hourly weather data in a text file. Sample input and output files are
 181 provided for assisting the user with preparation of data files with weather data in a format required by the BET program to
 182 calculate time series hourly and daily ET. The user can view the input (Fig. 3b) and output sample files by clicking on the
 183 Sample Input Format and Sample Output Format buttons provided on the page (Fig. 3a). BET calculates daily ET values,
 184 when the input file contains hourly weather data for one or more days, by summing up hourly ET values for both grass and
 185 alfalfa reference crops. Input parameters required for calculating times series hourly and daily ET are the same as those
 186 required for calculating a single hourly ET value (Fig. 2a).

187

Figure 3. Interactive pages for calculating hourly and daily ET_{ref} values from hourly meteorological data.

188

189 This hourly time-series page also has four tabs for displaying uploaded hourly input data as well as calculated hourly
 190 and daily ET_{os} and ET_{rs} in the built-in spreadsheet. The user can calculate eleven different statistics for each uploaded or
 191 calculated variable including mean, median, mode, and standard deviation. Figure 3c illustrates the hourly input and
 192 output in a spreadsheet format where the user can select data statistics. The user has the option of selecting one or more
 193 variables for calculating the statistics. The user can also display the variables in line graphs and scatter plots for QA/QC
 194 purposes. Figure 4(a-b) illustrates BET's graphing capabilities. The user can use these capabilities to identify outliers in
 195 the data. The interactive page for calculating daily ET_{os} and ET_{rs} is similar to that of the hourly time series page except
 196 there will be no tab for the hourly data. Data requirements for the daily ET_{ref} calculations are the same as those required
 197 for single calculations at a daily time-step.

198

Figure 4. Plotting capabilities of the Bushland Reference ET Calculator.

199

200 APPLICATION OF BET

201 To demonstrate the capability of BET, ET_{os} and ET_{rs} were calculated and compared against published values. Further, a

202 sensitivity evaluation of climate parameters on the calculation of ET_{os} and ET_{rs} was conducted using a long term climatic
 203 dataset. For this purpose, long term climatic data (1991-2008) from a weather station located at Bushland 10 miles west of
 204 Amarillo, Texas was used. This station is maintained by the TXHPET network and ASCE standardized PM equation based
 205 ET_{os} and ET_{rs} were available for this station for comparison purposes. Using the BET program, hourly ET_{os} and ET_{rs} were
 206 calculated and summed to get daily values.

207 To quantify the sensitivity of each climate parameter on ET_{ref} , a sensitivity coefficient (C_s) was calculated ($C_s =$
 208 CH_{ETos}/CH_{CV} ; where CH_{ETos} was the change in ET_{os} with respect to climate variable, and CH_{CV} was the change in climate
 209 variable) (Irmak et al., 2006). The C_s for each climate variable was calculated by dividing the value of change in ET_{os} or
 210 ET_{rs} calculated using the BET by the amount of increase or decrease in the value of the climate input parameter. A 25 W
 211 m^{-2} increase or decrease is considered equivalent to one unit for solar radiation and one unit increase or decrease for all
 212 other variables. Finally, sensitivity coefficients for all climate parameters were compared to determine sensitivity of ET to
 213 each parameter over different cropping seasons. The higher the C_s value for a climate parameter, the more sensitive the ET
 214 calculation was to variation in that parameter.

215

216
217
218
219

Figure 5. Daily average ET_{ref} sensitivity coefficients for air temperature (Air T), dew point temperature (Dew T), wind speed (WS), and solar radiation (SR).

220 Calculated ET_{os} and ET_{rs} values were matched with values reported by the [Texas High Plains ET Network between](#)
 221 [1991-2008](#) to the fourth decimal indicating that BET program calculated both ET_{os} and ET_{rs} accurately. Figure 5(a-b)
 222 illustrates the sensitivities of ET_{os} and ET_{rs} to variations in air and dew point temperatures, wind speed, and solar radiation,
 223 respectively. Greater values of sensitivity coefficients indicate greater impact of errors in data on the calculated ET_{ref}
 224 values. Individual parameters affected ET_{os} and ET_{rs} calculations. These sensitivities were greater during the summer
 225 period corresponding to the growing season for most crops. Wind speed was found to be the most impacting parameter
 226 followed by air temperature. However, solar radiation errors also significantly affected the ET calculation, especially
 227 during the mid-summer growing period. Dew point temperature generally indicated a lower impact, yet it also showed
 228 seasonal variation with an increased sensitivity coefficient during the mid-summer growing season.

229 SUMMARY

230 Reliable and accurate estimates of crop water use or crop ET are required for improving water use efficiency in
 231 irrigated agriculture. Crop ET is calculated by multiplying the grass or alfalfa reference ET by the appropriate crop
 232 coefficient. This paper demonstrates use of the Bushland Reference ET Calculator (BET) developed and distributed, at no
 233 cost, to interested users through the USDA-ARS web site (<http://www.cprl.ars.usda.gov/swmru-software-bretec.php>).
 234 BET's capability was demonstrated using a long term climatic dataset from a TXHPET network station. Plotting

235 capabilities were tested by plotting sample data. Although the BET was designed and developed mainly for use by
236 progressive producers and crop consultants to manage irrigation scheduling, it can also be used in educational training,
237 research, and other practical applications. At present, BET is made available to all PC-based operating systems.
238 Subsequent efforts are underway to develop BET for smart phone platforms such as the iPhone and Android operating
239 systems and further enhance capabilities of the Windows versions of the BET to include calculation of potential ET of
240 crops using crop coefficients.

241 **ACKNOWLEDGEMENTS**

242 This research was supported by the Ogallala Aquifer Program, a consortium between USDA–Agricultural Research
243 Service, Kansas State University, Texas AgriLife Research, Texas AgriLife Extension Service, Texas Tech University, and
244 West Texas A&M University. We would like thank Mr. Jerry Ennis, IT Administrator; Jerry Moorhead, Biological Science
245 Technician; and Travis Warzecha for their assistance in developing the Bushland reference ET Calculator.

Responses to AE and Reviewers' Comments

Associate Editor

Comments: The new user-friendly 'Calculator' for reference ET at multiple time scale is very useful for many scientists, Engineers, and water users. However, I found the write up can be improved by describing more clearly the principles of reference ET. Many users are not as familiar with the history of why there are FAO ETo, Grass ETos, Alfalfa ETrs.

Response: Agreed with the AE. The introduction section is revised to give more information on different methods and principles. However, we did not add any new equations that are already available (step by step) in the ASCE-EWRI manual.

Comments: Since the user can access a User's Manual, I suggest the authors discuss more of the science of reference ET, and it will be useful to provide a true application to show how the tool can be used to estimate ETref and actual ET for a cropland.

Response: There is abundant literature on the real science behind reference ET. We summarized with appropriate and selective citations for users who want to read more. However, we made an effort to add a little more information to questions that may arise in readers' mind. The software does not calculate the actual ET. We are hoping to add that capability in the near future.

Comments: I am not very clear why the authors present the sensitivity of the two models; I was unclear how the sensitivity was conducted.

Response: The ASCE-EWRI reference ET model is used to calculate potential ET for two reference crops: grass and alfalfa. This is the reason we presented sensitivity of two models. A case study with a real dataset is presented to demonstrate the capability of the software and importance of the accuracy of the data that is needed to estimate reference ET. A reference (Irmak et al., 2006) is provided for a more detailed step by step procedure on the sensitivity study. In addition, sensitivity methodology is also presented for ET experts.

Comments: I attached a file with editorial remarks.

Response: Summary comments (see above) made by the AE are basically derived from comments made on the manuscript. The manuscript is revised considering both summary and individual comments.

Reviewer: 1

Comment 1: How the BET tool become more friendly than other refET tools. Are other tools not so friendly for users? Why? Add more discussions.

Response: Please see lines 114-131 for this information

Comments 2: Is the result calculated by BET different from other tool or the measurement refET? How to ensure the result correct? Discuss more about the QA/QC.

Response: The Texas High Plains ET Network uses ASCE-EWRI method to estimate their reference ET values. Our values were matched to fourth decimal when we compared BET-calculated to values with historical data (1991-2008). We also compared with the testing dataset provided by the ASCE-EWRI manual (Allen et al., 2005). A line is added in the text to provide this information (Page 220-221).

Comment 3: Other modifications are remarked in the attach file.

Response: Revised the manuscript accordingly.

Comments: Authors have done an excellent job. The tool will very helpful for irrigation scheduling and water management.

Response: Thanks.
